

Comp 324/424 - Client-side Web Design

Spring Semester 2019 - Week 14

Dr Nick Hayward

Final Demo and Presentation

- presentation and demo - live working app...
 - *due on Monday 22nd April 2019 @ 4.15pm*
 - **NO** content management systems (CMSs) such as Drupal, Joomla, WordPress...
 - **NO** PHP, Python, Ruby, C# & .Net, Go, XML...
 - **NO** CSS frameworks, such as Bootstrap, Foundation, Materialize...
- explain chosen app's logic and structure
 - *data store, API, deferred patterns &c.*
 - *any data visualisations used*
 - ...
- must implement data from either
 - *self hosted (MongoDB, Redis...)*
 - *APIs*
 - *cloud services, storage (Firebase, Heroku, mLab &c.)*
 - **NO** SQL...
- explain design decisions
 - *describe patterns used in design of UI and interaction*
 - *layout choices...*
- show and explain implemented differences from DEV week
 - *where and why did you update the app?*
 - *perceived benefits of the updates?*
- how did you respond to peer review?
- anything else useful for final assessment...
- consider outline of content from final report outline
- ...

All project code must be pushed to a repository on GitHub.

n.b. present your own work contributed to the project, and its development...

Final Report

Report due on 29th April 2019 by 4.15pm

- final report outline - coursework section of website
 - *PDF*
 - *group report*
 - ***extra individual report*** - *optional*
- include repository details for project code on GitHub

JavaScript - Prototype

intro

- along with the following traits of JS (ES6 ...),
- functions as first-class *objects*
- versatile and useful structure of functions with closures
- combine generator functions with promises to help manage async code
- `async` & `await`...
- *prototype* object may be used to delegate the search for a particular property
- a *prototype* is a useful and convenient option for defining properties and functionality
- accessible to other objects
- a *prototype* is a useful option for replicating many concepts in traditional object oriented programming

JavaScript - Prototype

understanding prototypes

- in JS, we may create objects, e.g. using *object-literal* notation
- a simple value for the first property
- a function assigned to the second property
- another object assigned to the third object

```
let testObject = {  
  property1: 1,  
  prooerty2: function() {},  
  property3: {}  
}
```

- as a dynamic language, JS will also allow us to
- modify these properties
- delete any not required
- or simply add a new one as necessary
- this dynamic nature may also completely change the properties in a given object
- this issue is often solved in traditional object-oriented languages using inheritance
- in JS, we can use *prototype* to implement inheritance

JavaScript - Prototype

basic idea of prototypes

- every *object* can have a reference to its *prototype*
- a delegate object with properties - default for child objects
- JS will initially search the object for a property
- then, search the *prototype*
- i.e. prototype is a fall back object to search for a given property &c.

```
const object1 = { title: 'the glass bead game' };
const object2 = { author: 'herman hesse' };

console.log(object1.title);

Object.setPrototypeOf(object1, object2);

console.log(object1.author);
```

- in the above example, we define two objects
- properties may be called with standard object notation
- can be modified and mutated as standard
- use `setPrototypeOf ()` to set and update object's prototype
- e.g. `object1` as object to update
- `object2` as the object to set as prototype
- if requested property is not available on `object1`
- JS will search defined prototype...
- `author` available as property of prototype for `object1`
- demo - basic prototype

JavaScript - Prototype

prototype inheritance

- *Prototypes*, and their properties, can also be inherited
- creates a chain of inheritance...
- e.g.

```
const object1 = { title: 'the glass bead game' };
const object2 = { author: 'herman hesse' };
const object3 = { genre: 'fiction' };

console.log(object1.title);

Object.setPrototypeOf(object1, object2);
Object.setPrototypeOf(object2, object3);

console.log(object1.author);
console.log(`genre from prototype chain = ${object1.genre}`); // use template lit
```

- object1 has access to the prototype of its parent, object2
- a property search against object1 will now include its own prototype, object2
- and its prototype as well, object3
- output for object1.genre will return the value stored in the property on object3
- demo - basic set prototype

JavaScript - Prototype

object constructor & prototypes

- object-oriented languages, such as Java and C++, include a class constructor
- provides known encapsulation and structuring
- constructor is initialising an object to a known initial state...
- i.e. consolidate a set of properties and methods for a class of objects in one place
- JS offers such a mechanism, although in a slightly different form to Java, C++ &c.
- JS still uses the new operator to instantiate new objects via constructors
- JS does not include a true class definition comparable to Java &c.
- ES6 `class` is syntactic sugar for the `prototype`...
- new operator in JS is applied to a constructor function
- this triggers the creation of a new object

JavaScript - Prototype

prototype object

- in JS, every function includes their own prototype object
- set automatically as the prototype of any created objects
- e.g.

```
//constructor for object  
function LibraryRecord() {  
  //set default value on prototype  
  LibraryRecord.prototype.library = 'castalia';  
}  
  
const bookRecord = new LibraryRecord();  
  
console.log(bookRecord.library);
```

- likewise, we may set a default method on an instantiated object's prototype
- demo - basic prototype object

JavaScript - Prototype

instance properties

- as JS searches an object for properties, values or methods
- instance properties will be searched before trying the prototype
- a known order of precedence will work.
- e.g.

```
//constructor for object
function LibraryRecord() {
  // set property on instance of object
  this.library = 'waldzell';

  //set default value on prototype
  LibraryRecord.prototype.library = 'castalia';
}

const bookRecord = new LibraryRecord();

console.log(bookRecord.library);
```

- `this` refers directly to the newly created object
- properties in constructor created directly on instantiated object
- e.g. instance of `LibraryRecord()`
- search for `library` property against object
- do not need to search against prototype for this example
- known side-effect
- instantiate multiple objects with this constructor
- each object gets its own copy of the constructor's properties & access to same prototype
- may end up with multiple copies of same properties in memory
- if replication is required or likely
- more efficient to store properties & methods against the prototype

- demo - basic prototype object properties

JavaScript - Prototype

side effects of JS dynamic nature

- JS is a dynamic language
- properties can be added, removed, modified...
- dynamic nature is true for prototypes
- function prototypes
- object prototypes

```
//constructor for object
function LibraryRecord() {
  // set property on instance of object
  this.library = 'waldzell';
}

// create instance of LibraryRecord - call constructor with `new` operator
const bookRecord1 = new LibraryRecord();

// check output of value for library property from constructor
console.log(`this library = ${bookRecord1.library}`);

// add method to prototype after object created
LibraryRecord.prototype.updateLibrary = function() {
  return this.retreat = 'mariafels';
};

// check prototype updated with new method
console.log(`this retreat = ${bookRecord1.updateLibrary()}`);

// then overwrite prototype - constructor for existing object unaffected...
LibraryRecord.prototype = {
  archive: 'mariafels',
  order: 'benedictine'
};

// create instance object of LibraryRecord...with updated prototype
const bookRecord2 = new LibraryRecord();

// check output for second instance object
console.log(`updated archive = ${bookRecord2.archive} and order = ${bookRecord2.o
// check output for second instance object - library
console.log(`second instance object - library = ${bookRecord2.library}`);
// check if prototype updated for first instance object - NO
```

```
console.log(`first instance object = ${bookRecord1.order}`);  
// manual update to prototype for first instance object still available  
console.log(`this retreat2 = ${bookRecord1.updateLibrary()}`);  
  
// check prototype has been fully overwritten - e.g. `updateLibrary()` no longer  
try {  
  // updates to original prototype are overridden - error is returned for second in  
  console.log(`this retreat = ${bookRecord2.updateLibrary()}`);  
} catch(error) {  
  console.log(`modified prototype not available for new object...\n ${error}`);  
}
```

- demo - basic prototype dynamic

JavaScript - Prototype

object typing via constructors

- check function used as a constructor to instantiate an object
- using constructor property

```
//constructor for object
function LibraryRecord() {
  //set default value on prototype
  LibraryRecord.prototype.library = 'castalia';
}

// create instance object for libraryRecord
const bookRecord = new LibraryRecord();

// output constructor for instance object
console.log(`constructor = ${bookRecord.constructor}`);

// check if function was constructor (use ternary conditional)
const check = bookRecord.constructor === LibraryRecord ? true : false;
// output result of check
console.log(check);
```

- demo - basic constructor check

JavaScript - Prototype

instantiate a new object using a constructor reference

- use a constructor to create a new instance object
- also use `constructor ()` of new object to create another object
- second object is still an object of the original constructor

```
//constructor for object  
function LibraryRecord() {  
    //set default value on prototype  
    LibraryRecord.prototype.library = 'castalia';  
}  
  
const bookRecord = new LibraryRecord();  
const bookRecord2 = new bookRecord.constructor();
```

JavaScript - Prototype

achieving inheritance

- *Inheritance* enables re-use of an object's properties by another object
- helps us efficiently avoid repetition of code and logic
- improving reuse and data across an application
- in JS, a prototype chain to ensure inheritance works beyond simply copying prototype properties
- e.g. a book in a corpus, a corpus in an archive, an archive in a library...

JavaScript - Prototype

inheritance with prototypes - part I

- *inheritance* in JS
- create a prototype chain using an instance of an object as prototype for another object
- e.g.

```
SubClass.prototype = new SuperClass()
```

- this pattern works as a prototype chain for inheritance
- prototype of SubClass instance as an instance of SuperClass
- prototype will have all the properties of SuperClass
- SuperClass may also have properties from its superclass...
- prototype chain created of expected inheritance

JavaScript - Prototype

inheritance with prototypes - part 2

- e.g. inheritance achieved by setting prototype of Archive to instance of Library object

```
//constructor for object
function Library() {
    // instance properties
    this.type = 'library';
    this.location = 'waldzell';
}

// constructor for Archive object
function Archive(){
    // instance property
    this.domain = 'gaming';
}

// update prototype to parent Library - instance relative to parent & child
Archive.prototype = new Library();

// instantiate new Archive object
const archiveRecord = new Archive();

// check instance object - against constructor
if (archiveRecord instanceof Archive) {
    console.log(`archive domain = ${archiveRecord.domain}`);
}

// check instance of archiveRecord - instance of Library & Archive
if (archiveRecord instanceof Library) {
    // type property from Library
    console.log(`Library type = ${archiveRecord.type}`);
    // domain property from Archive
    console.log(`Archive domain = ${archiveRecord.domain}`);
}
```

JavaScript - Prototype

issues with overriding the constructor property

- setting Library object as defined prototype for Archive constructor

```
Archive.prototype = new Library();
```

- connection to Archive constructor **lost** - we may check constructor

```
// check constructor used for archiveRecord object
if (archiveRecord.constructor === Archive) {
  console.log('constructor found on Archive...');
} else {
  // Library constructor output - due to prototype
  console.log(`Archive constructor = ${archiveRecord.constructor}`);
}
```

- Library constructor will be returned
- *n.b.* may become an issue - constructor property may be used to check original function for instantiation
- demo - inheritance with prototype

JavaScript - Prototype

some benefits of overriding the constructor property

```
//constructor for object
function Library() {
    // instance properties
    this.type = 'library';
    this.location = 'waldzell';
}

// extend prototype
Library.prototype.addArchive = function(archive) {
    console.log(`archive added to library - ${archive}`);
    // add archive property to instantiate object
    this.archive = archive;
    // add property to Library prototype
    Library.prototype.administrator = 'knechts';
}

// constructor for Archive object
function Archive(){
    // instance property
    this.domain = 'gaming';
}

// update prototype to parent Library - instance relative to parent & child
Archive.prototype = new Library();

// instantiate new Archive object
const archiveRecord = new Archive();
// call addArchive on Library prototype
archiveRecord.addArchive('mariafels');

// check instance object - against constructor
if (archiveRecord instanceof Archive) {
    console.log(`archive domain = ${archiveRecord.domain}`);
}

// check constructor used for archiveRecord object
if (archiveRecord.constructor === Archive) {
    console.log('constructor found on Archive...');
} else {
    console.log(`Archive constructor = ${archiveRecord.constructor}`);
    console.log(`Archive domain = ${archiveRecord.domain}`);
    console.log(`Archive = ${archiveRecord.archive}`);
    console.log(`Archive admin = ${archiveRecord.administrator}`);
}
```

```

}

// check instance of archiveRecord - instance of Library & Archive
if (archiveRecord instanceof Library) {
    // type property from Library
    console.log(`Library type = ${archiveRecord.type}`);
    // domain property from Archive
    console.log(`Archive domain = ${archiveRecord.domain}`);
}

// instantiate another Archive object
const archiveRecord2 = new Archive();
// output instance object for second archive
console.log('Archive2 object = ', archiveRecord2);
// check if archiveRecord2 object has access to updated archive property...NO
console.log(`Archive2 = ${archiveRecord2.archive}`);
// check if archiveRecord2 object has access to updated administrator property...Y
console.log(`Archive2 administrator = ${archiveRecord2.administrator}`);

```

- demo - inheritance with prototype - updated

JavaScript - Prototype

configure object properties - part 1

- each object property in JS is described with a **property descriptor**
- use such descriptors to configure specific keys, e.g.
- *configurable* - boolean setting
 - *true* = property's descriptor may be changed and the property deleted
 - *false* = no changes &c.
- *enumerable* - boolean setting
 - *true* = specified property will be visible in a *for-in* loop through object's properties
- *value* - specifies value for property (default is undefined)
- *writable* - boolean setting
 - *true* = the property value may be changed using an assignment
- *get* - defines the getter function, called when we access the property
 - **n.b.** can't be defined with *value* and *writable*
- *set* - defines the setter function, used whenever an assignment is made to the property
 - **n.b.** can't be defined with *value* and *writable*
- e.g. create following property for an object

```
archive.type = 'private';
```

- `archive`
- will be *configurable*, *enumerable*, *writable*
- with a value of *private*
- *get* and *set* will currently be undefined

JavaScript - Prototype

configure object properties - part 2

- to update or modify a property configuration use built-in `Object.defineProperty()` method
- this method takes an object, which may be used to
- define or update the property
- define or update the name of the property
- define a property descriptor object
 - e.g.

```
// empty object
const archive = {};

// add properties to object
archive.name = "waldzell";
archive.type = "game";

// define property access, usage, &c.
Object.defineProperty(archive, "access", {
  configurable: false,
  enumerable: false,
  value: true,
  writable: true
});

// check access to new property
console.log(`${archive.access}, access property available on the object...`);

/*
 * check we can't access new property in loop
 * - for..in iterates over enumerable properties
 */
for (let property in archive) {
  // log enumerable
  console.log(`key = ${property}, value = ${archive[property]}`);
}

/*
 * plain object values not iterable...
 * - returns expected TypeError - archive is not iterable
 */
```

```
for (let value of archive) {  
  // value not logged...  
  console.log(value);  
}
```

- demo - configure object properties

JavaScript - Prototype

using ES Classes

- ES6 provides a new `class` keyword
- enables object creation and adds in inheritance
- it's *syntactic sugar* for the prototype and instantiation of objects
 - e.g.

```
// class with constructor & methods
class Archive {
  constructor(name, admin) {
    this.name = name;
    this.admin = admin;
  }
  // class method
  static access() {
    return false;
  }
  // instance method
  administrator() {
    return this.admin;
  }
}

// instantiate archive object
const archive = new Archive('Waldzell', 'Knechts');

// check parameter usage with class
const nameCheck = archive.name === `Waldzell` ? archive.name : false;

// log archive name
console.log(`class archive name = ${nameCheck}`);
// call class method
console.log(Archive.access());
// call instance method
console.log(`archive administrator = ${archive.administrator()}`);
```

- demo - basic ES Class

JavaScript - Prototype

ES classes as syntactic sugar

- classes in ES6 are simply syntactic sugar for prototypes.
- a prototype implementation of previous Archive class, and usage...
- e.g.

```
// constructor function
function Archive(name, admin) {
  this.name = name;
  this.admin = admin;

  // instance method
  this.administrator = function () {
    return this.admin;
  }

  // add property to constructor
  Archive.access = function() {
    return false;
  };
}

// instantiate object - pass arguments
const archive = new Archive('Waldzell', 'Knechts');

// check parameter usage with ternary conditional...
const nameCheck = archive.name === `Waldzell` ? archive.name : false;

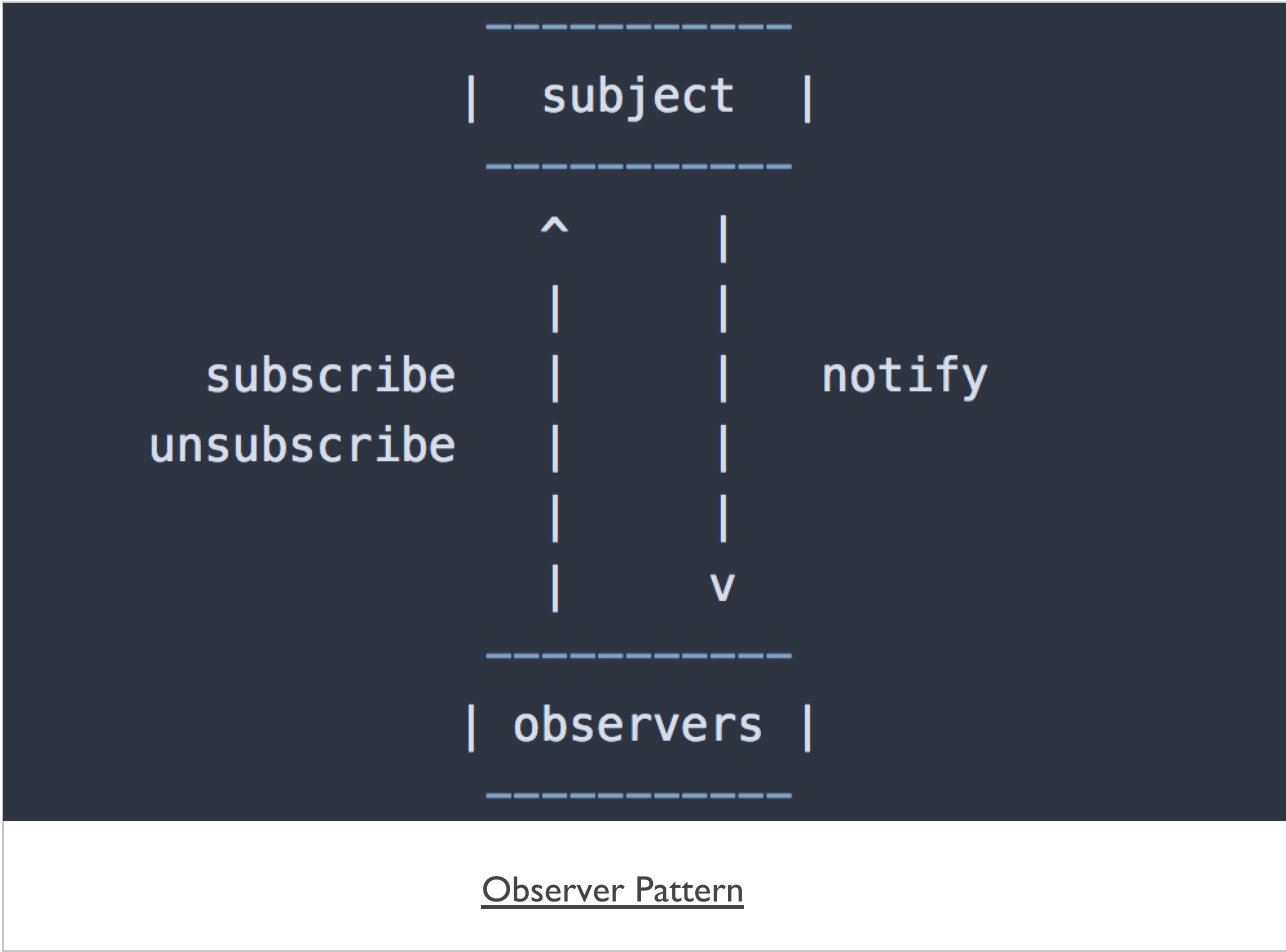

// output name check...
console.log(`prototype archive name = ${nameCheck}`);
// call constructor only method
console.log(Archive.access());
// call instance method
console.log(`archive administrator = ${archive.administrator()}`);
```

- demo - basic Prototype equivalent

Design Patterns - Observer - intro

- *observer* pattern is used to help define a *one to many* dependency between objects
- as **subject** (object) changes state
 - *any dependent **observers** (object/s) are then notified automatically*
 - *and then may update accordingly*
- managing changes in state to keep app in sync
- creating bindings that are event driven
 - *instead of standard push/pull*
- standard usage for this pattern with bindings
 - *one to many*
 - *one way*
 - *commonly event driven*

Image - Observer Pattern

Design Patterns - Observer - notifications

- observer pattern creates a model of event subscription with notifications
- benefit of this pattern
 - *tends to promote loose coupling in component design and development*
- pattern is used a lot in JavaScript based applications
 - *user events are a common example of this usage*
- pattern may also be referenced as *Pub/Sub*
 - *there are differences between these patterns - be careful...*

Design Patterns - Observer - Usage

The observer pattern includes two primary objects,

- **subject**

- *provides interface for observers to subscribe and unsubscribe*
- *sends notifications to observers for changes in state*
- *maintains record of subscribed observers*
- *e.g. a click in the UI*

- **observer**

- *includes a function to respond to subject notifications*
- *e.g. a handler for the click*

Design Patterns - Observer - Example

```
// constructor for subject
function Subject () {
  // keep track of observers
  this.observers = [];
}

// add subscribe to constructor prototype
Subject.prototype.subscribe = function(fn) {
  this.observers.push(fn);
};

// add unsubscribe to constructor prototype
Subject.prototype.unsubscribe = function(fn) {
  // ...
};

// add broadcast to constructor prototype
Subject.prototype.broadcast = function(status) {
  // each subscriber function called in response to state change...
  this.observers.forEach((subscriber) => subscriber(status));
};

// instantiate subject object
const domSubject = new Subject();

// subscribe & define function to call when broadcast message is sent
domSubject.subscribe((status) => {
  // check dom load
  let domCheck = status === true ? `dom loaded = ${status}` : `dom still loading.`;
  // log dom check
  console.log(domCheck)
});

document.addEventListener('DOMContentLoaded', () => domSubject.broadcast(true));
```

Design Patterns - Observer - Example

- Observer - Broadcast, Subscribe, & Unsubscribe

Design Patterns - Pub/Sub - intro

- variation of standard *observer* pattern is *publication and subscription*
 - *commonly known as PubSub pattern*
- popular usage in JavaScript
- *PubSub* pattern publishes a *topic* or event channel
- publication acts as a *mediator* or event system between
 - *subscriber objects wishing to receive notifications*
 - *and publisher object announcing an event*
- easy to define specific events with event system
- events may then pass custom arguments to a subscriber
- trying to avoid potential dependencies between objects
 - *subscriber objects and the publisher object*

Design Patterns - Pub/Sub - abstraction

- inherent to this pattern is the simple abstraction of responsibility
- publishers are unaware of nature or type of subscribers for messages
- subscribers are unaware of the specifics for a given publisher
- subscribers simply identify their interest in a given topic or event
 - *then receive notifications of updates for a given subscribed channel*
- primary difference with *observer* pattern
 - *PubSub abstracts the role of the subscriber*
- *subscriber* simply needs to handle data broadcasts by a *publisher*
- creating an abstracted event system between objects
 - *abstraction of concerns between publisher and subscriber*

Image - Publish/Subscribe Pattern

PubSub Pattern

Design Patterns - Pub/Sub - benefits

- *observer and PubSub patterns help developers*
 - *better understanding of relationships within an app's logic and structure*
- *need to identify aspects of our app that contain direct relationships*
- *many direct relationships may be replaced with patterns*
 - *subjects and observers*
 - *publishers and observers*
- *tightly coupled code can quickly create issues*
 - *maintenance, scale, modification, clarity of code and logic...*
 - *seemingly minor changes may often create a cascade or waterfall effect in code*
- *a known side effect of tightly couple code*
 - *frequent need to mock usage &c. in testing*
 - *time consuming and error prone as app scales...*
- *PubSub helps create smaller, loosely coupled blocks*
 - *helps improve managment of an app*
 - *promotes code reuse*

Design Patterns - Pub/Sub - basic example - part I - event system

```
// constructor for pubsub object
function PubSub () {
  this.pubsub = {};
}

// publish - expects topic/event & data to send
PubSub.prototype.publish = function (topic, data) {
  // check topic exists
  if (!this.pubsub[topic]){
    console.log(`publish - no topic...`);
    return false;
  }
  // loop through pubsub for specified topic - call subscriber functions...
  this.pubsub[topic].forEach(function(subscriber) {
    subscriber(data || {});
  });
};

// subscribe - expects topic/event & function to call for publish notification
PubSub.prototype.subscribe = function (topic, fn) {
  // check topic exists
  if (!this.pubsub[topic]) {
    // create topic
    this.pubsub[topic] = [];
    console.log(`pubsub topic initialised...`);
  }
  else {
    // log output for existing topic match
    console.log(`topic already initialised...`);
  }
  // push subscriber function to specified topic
  this.pubsub[topic].push(fn);
};
```

Design Patterns - Pub/Sub - basic example - part 2 - usage

```
// basic log output
var logger = data => { console.log( `logged: ${data}` ); };

// test function for subscriber
var domUpdater = function (data) {
  document.getElementById('output').innerHTML = data;
}

// instantiate object for PubSub
const pubSub = new PubSub();

// subscriber tests
pubSub.subscribe( 'test_topic', logger );
pubSub.subscribe( 'test_topic2', domUpdater );
pubSub.subscribe( 'test_topic', logger );

// publisher tests
pubSub.publish('test_topic', 'hello subscribers of test topic...');
pubSub.publish('test_topic2', 'update notification for test topic2...');
```

■ Demo - Pub/Sub

JavaScript - modular design

ES Module pattern - intro

- simpler and easier to work with than CommonJS
 - *in most examples...*
- JavaScript `strict` mode is enabled by default
- `strict` mode helps with language usage - check for poor usage
 - *stops hoisting of variables*
 - *variables must be declared*
 - *function parameters must have unique name*
 - *assignment to read-only properties throws errors*
 - ...
- modules are exported with `export` statements
- modules are imported with `import` statements

JavaScript - modular design

ES Module pattern - export statements

- ES6 modules are individual files
 - *expose an API using `export` statements*
- declarations are scoped to the local module
- e.g. variables declared inside a module
 - *not available to other modules*
 - *need to be explicitly exported in module API*
 - *need to be imported for usage in another module*
- export statements may only be added to *top-level* of a module
 - *e.g. not in function expression &c.*
- cannot dynamically define and expose API using methods
 - *unlike CommonJS module system - Node.js &c.*

JavaScript - modular design

ES Module pattern - export default

- common option is to export a default binding, e.g.

```
export default `hello world`
```

```
export default {  
  name: 'Alice',  
  place: 'Wonderland'  
}
```

```
export default [  
  'Alice', 'Wonderland'  
]
```

```
export default function name() {  
  ...  
}
```

JavaScript - modular design

ES Module pattern - bindings

- ES modules export **bindings**
 - *not values or references*
- e.g. an export of `count` variable from a module
 - *`count` is exported as a binding*
 - *export is bound to `count` variable in the module*
 - *value is subject to changes of `count` in module*
- offers flexibility to exported API
 - *e.g. `count` might originally be bound to an object*
 - *then changed to an array...*
- other modules consuming this export
 - *they would see change as `count` is modified*
 - *modified in module and exported...*
- **n.b.** take care with this usage pattern
 - *useful for counters, logs &c.*
 - *can cause issues with API usage for a module*

JavaScript - modular design

ES Module pattern - named export

- we may define bindings for export
- instead of assigning properties to implicit export object
 - e.g.

```
export let counter = 0
export const count = () => counter++
```

- cannot refactor this example for named export
 - *syntax error will be thrown*
 - e.g.

```
let counter = 0
const count = () => counter++
export counter // this will return syntax error
export count
```

- rigid syntax helps with analysis, parsing
 - *static analysis for ES modules*

JavaScript - modular design

ES Module pattern - export lists

- lists provide a useful solution to previous refactor issue
- syntax for list export easy to parse
- export lists of named *top-level* declarations
 - *variables &c.*
- e.g.

```
let counter = 0
const count = () => counter++
export { counter, count }
```

- also rename binding for export, e.g.

```
let counter = 0
const count = () => counter++
export { counter, count as increment }
```

- define default with export list, e.g.

```
let counter = 0
const count = () => counter++
export { counter as default, count as increment }
```

JavaScript - modular design

ES Module pattern - export from ...

- expose another module's API using `export from...`
 - *i.e. a kind of pass through...*
- e.g.

```
export { increment } from './myCounter.js'
```

- bindings are not imported into module's local scope
- current module acts as conduit, passing bindings along export/import chain...
- module does not gain direct access to `export from ...` bindings
 - *e.g. if we call `increment` it will throw a `ReferenceError`*
- aliases are also possible for bindings with `export from...`
 - e.g.

```
export { increment as addition } from './myCounter.js'
```

JavaScript - modular design

ES Module pattern - import statements

- use `import` to load another module
- `import` statements are only allowed in top level of module definition
 - *same as `export` statements*
 - *helps compilers simplify module loading &c.*
- import default exports
 - *give default export a name as it is imported*
 - e.g.

```
import counter from './myCounter.js'
```

- importing binding to `counter`
- syntax different from declaring a JS variable

JavaScript - modular design

ES Module pattern - import named exports

- also imported any named exports
 - *import more than just default exports*
- named import is wrapped in braces
 - e.g.

```
import { increment } from './myCounter.js'
```

- also import multiple named exports
 - e.g.

```
import { increment, decrement } from './myCounter.js'
```

- import aliases are also supported
 - e.g.

```
import { increment as addition } from './myCounter.js'
```

- combine default with named
 - e.g.

```
import counter, { increment } from './myCounter.js'
```

JavaScript - modular design

ES Module pattern - import with wildcard

- we may also import using the *wildcard* operator
 - e.g.

```
import * as counter from './myCounter.js'  
counter.increment()
```

- name for wildcard import acts like object for module
- call module exports on wildcard

```
import * as counter from './myCounter.js'  
counter.increment()
```

- common pattern for working with libraries &c.

JavaScript - modular design

ES Module pattern - benefits & practical usage

- offers ability to explicitly publish an API
 - *keeps module content local unless explicitly exported*
- similar function to getters and setters
 - *explicit way in and out of modules*
 - *explicit options for reading and updating values...*
- code becomes simpler to write and manage
 - *module offers encapsulation of code*
- import binding to variable, function &c.
 - *then use it as normal...*
- removes need for encapsulation in main JS code
 - *e.g. with patterns such as IIFE...*
- *n.b.* need to be careful how we use modules
 - *e.g. priority for access, security, testing &c.*
 - *all now moved to individual modules...*

JavaScript - modular design

ES Module pattern - Lib structure

- Modules in JavaScript are not a new concept
 - e.g. *CommonJS* is a popular option for modular development with *Node.js*
- a built-in option for plain JavaScript, *ES Modules*.
- use this option to develop and structure custom module libraries
- e.g.
 - *abstract utility modules*
 - *custom draw libraries*
 - *game renderers*
 - ...

JavaScript - modular design

ES Module pattern - JS library

- an example JS library - define the following directory structure

```
.
|-- lib
|   |-- spire
|   |   |-- helpers
|   |   |   |-- log.js
|   |   |   |-- spire.js
|   |-- main.js
|   ...
```

- lib directory contains custom JS libraries, which may then be imported for use within an app
- for app usage, we might structure it as follows

```
.
|-- lib
|   |-- spire
|   |   |-- helpers
|   |   |   |-- log.js
|   |   |   |-- spire.js
|-- index.html
|-- main.js
|   ...
```

JavaScript - modular design

ES Module pattern - JS library - main.js

- `main.js` file is loaded from the `index.html` file
 - *acts as the loader file for JS in an example app*
- also import example *Spire* JS library into an app using this main loader file, e.g.

```
import Spire from './lib/spire/spire.js';
```

- `Spire` object is the access point to the exported methods and variables for custom JS library

JavaScript - modular design

ES Module pattern - JS library - basic usage

- a custom JS library may then be accessed using this `Spire` object
- e.g. we might call a method from the library

```
const greeting = 'greetings from the planet Earth';  
// basic log to console  
Spire.log(`${greeting}...we wish you well`);
```

- custom method `log ()` provides a reusable method
 - e.g. use for various logging options in the application
- might also call the following method using the same pattern

```
Spire.dir({ 'name': 'test dir logger...' });
```

JavaScript - modular design

ES Module pattern - JS library - module usage

- sample usage might include such *helpers*
 - we may package in the directory *spire/helpers/*
 - e.g., we currently have a *log.js* module for various custom loggers

```
// basic logger to console
function log(value, ...values) {
  const logValue = console.log(value, ...values);

  return logValue;
}

// directory logger to console
function dir(value, ...values) {
  const dirValue = console.dir(value, ...values);

  return dirValue;
}
```

- we may then simply export these methods from the *log.js* module, e.g.

```
export {
  log,
  dir
}
```

- interface for this module has now been defined relative to the above exported modules

JavaScript - modular design

ES Module pattern - JS library - import modules

- import this module
 - *allow a module to use these exported methods*
 - *interact with the exposed interface*
- as part of the JS library structure we may define
 - *a root module for organising a unified interface for the overall library*
- e.g. use the module `spire.js` to import required modules and their interfaces

```
import * as loggers from './helpers/log.js';
```

- then define a `Spire` object for the overall library, e.g.

```
const Spire = {  
  log: loggers.log,  
  dir: loggers.dir,  
}
```

- this is then exported as the general interface for the `Spire JS` library, e.g.

```
export default Spire;
```

Responsive Design & Development - Modular Designs

Fun Exercise

Three responsive designs,

- Modular designs -
<http://linode4.cs.luc.edu/teaching/cs/demos/424/gifs/modular/>
 - *Home Design*
 - *Reminders*
 - *Watches*

For each design, consider the following

- define perceived modules for each app
 - *where might you use a module?*
- what type of modules can you define in each app?
 - *e.g. logical, structural, design, performance...*
- from a developer perspective
 - *consider primary modular groupings*
 - *does each module purpose help with testing?*
 - *can each module be decoupled from app?*
 - *e.g. test and use outside of current app...*

~ 10 minutes

Data visualisation

intro - part I

- data visualisation - study of how to visually communicate and analyse data
- covers many disparate aspects
 - *including infographics, exploratory tools, dashboards...*
- already some notable definitions of data visualisation
- one of the better known examples,

"Data visualisation is the representation and presentation of data that exploits our visual perception in order to amplify cognition."

(Kirk, A. "Data Visualisation: A successful design process." Packt Publishing. 2012.)

- several variants of this general theme exist
 - *the underlying premise remains the same*
- simply, data visualisation is a visual representation of the underlying data
- visualisation aims to impart a better understanding of this data
 - *by association, its relevant context*

Data visualisation

intro - part 2

- an inherent flip-side to data visualisation
- without a correct understanding of its application
 - *it can simply impart a false perception, and understanding, on the dataset*
- run the risk of creating many examples of standard **areal unit** problem
 - *perception often based on creator's base standard and potential bias*
- inherently good at seeing what we want to see
- without due care and attention visualisations may provide false summations of the data

Data visualisation

types - part I

- many different ways to visualise datasets
 - *many ways to customise a standard infographic*
- some standard examples that allow us to consider the nature of visualisations
 - *infographics*
 - *exploratory visualisations*
 - *dashboards*
- perceived that data visualisation is simply a variation between
 - *infographics, exploratory tools, charts, and some data art*

I. infographics

- *well suited for representing large datasets of contextual information*
- *often used in projects more inclined to exploratory data analysis,*
- *tend to be more interactive for the user*
- *data science can perceive infographics as improper data visualisation because*
- *they are designed to guide a user through a story*
- *the main facts are often already highlighted*
- **NB:** *such classifications often still only provide tangible reference points*

Data visualisation

types - part 2

2. exploratory visualisations

- *more interested in the provision of tools to explore and interpret datasets*
- *visualisations can be represented either static or interactive*
- *from a user perspective these charts can be viewed*
- *either carefully*
- *simply become interactive representations*
- *both perspectives help a user discover new and interesting concepts*
- *interactivity may include*
- *option for the user to filter the dataset*
- *interact with the visualisation via manipulation of the data*
- *modify the resultant information represented from the data*
- *often perceived as more objective and data oriented than other forms*

3. dashboards

- *dense displays of charts*
- *represent and understand a given issue, domain...*
- *as quickly and effectively as possible*
- *examples of dashboards*
- *display of server logs, website users, business data...*

Data visualisation

Dashboards - intro

- dashboards are dense displays of charts
- allow us to represent and understand the key **metrics** of a given issue
 - *as quickly and effective as possible*
 - *eg: consider display of server logs, website users, and business data...*
- one definition of a dashboard is as follows,

"A dashboard is a visual display of the most important information needed to achieve one or more objective; consolidated and arranged on a single screen so the information can be monitored at a glance."

Few, Stephen. Information Dashboard Design: The Effective Visual Communication of Data. O'Reilly Media. 2006.

- dashboards are visual displays of information
 - *can contain text elements*
 - *primarily a visual display of data rendered as meaningful information*

Data visualisation

Dashboards - intro

- information needs to be consumed quickly
- often simply no available time to read long annotations or repeatedly click controls
- information needs to be visible, and ready to be consumed
- dashboards are normally presented as a complementary environment
- an option to other tools and analytical/exploratory options
- design issues presented by dashboards include effective distribution of available space
- compact charts that permit quick data retrieval are normally preferred
- dashboards should be designed with a purpose in mind
- generalised information within a dashboard is rarely useful
- display most important information necessary to achieve their defined purpose
- a dashboard becomes a central view for collated data
- represented as meaningful information

Data visualisation

Dashboards - good practices

- to help promote our information
 - *need to design the dashboard to fully exploit available screen space*
- need to use this space to help users absorb as much information as possible
- some visual elements more easily perceived and absorbed by users than others
- some naturally convey and communicate information more effectively than others
- such attributes are known as **pre-attentive attributes of visual perception**
- for example,
 - *colour*
 - *form*
 - *position*

Data visualisation

Dashboards - visual perception

■ pre-attentive attributes of visual perception

1. Colour

- *many different colour models currently available*
- *most useful relevant to dashboard design is the HSL model*
- *this model describes colour in terms of three attributes*
 - *hue*
 - *saturation*
 - *lightness*
- *perception of colour often depends upon context*

2. Form

- *correct use of length, width, and general size can convey quantitative dimensions*
- *each with varying degrees of precision*
- *use the Laws of Prägnanz to manipulate groups of similar shapes and designs*
- *thereby easily grouping like data and information for the user*

3. Position

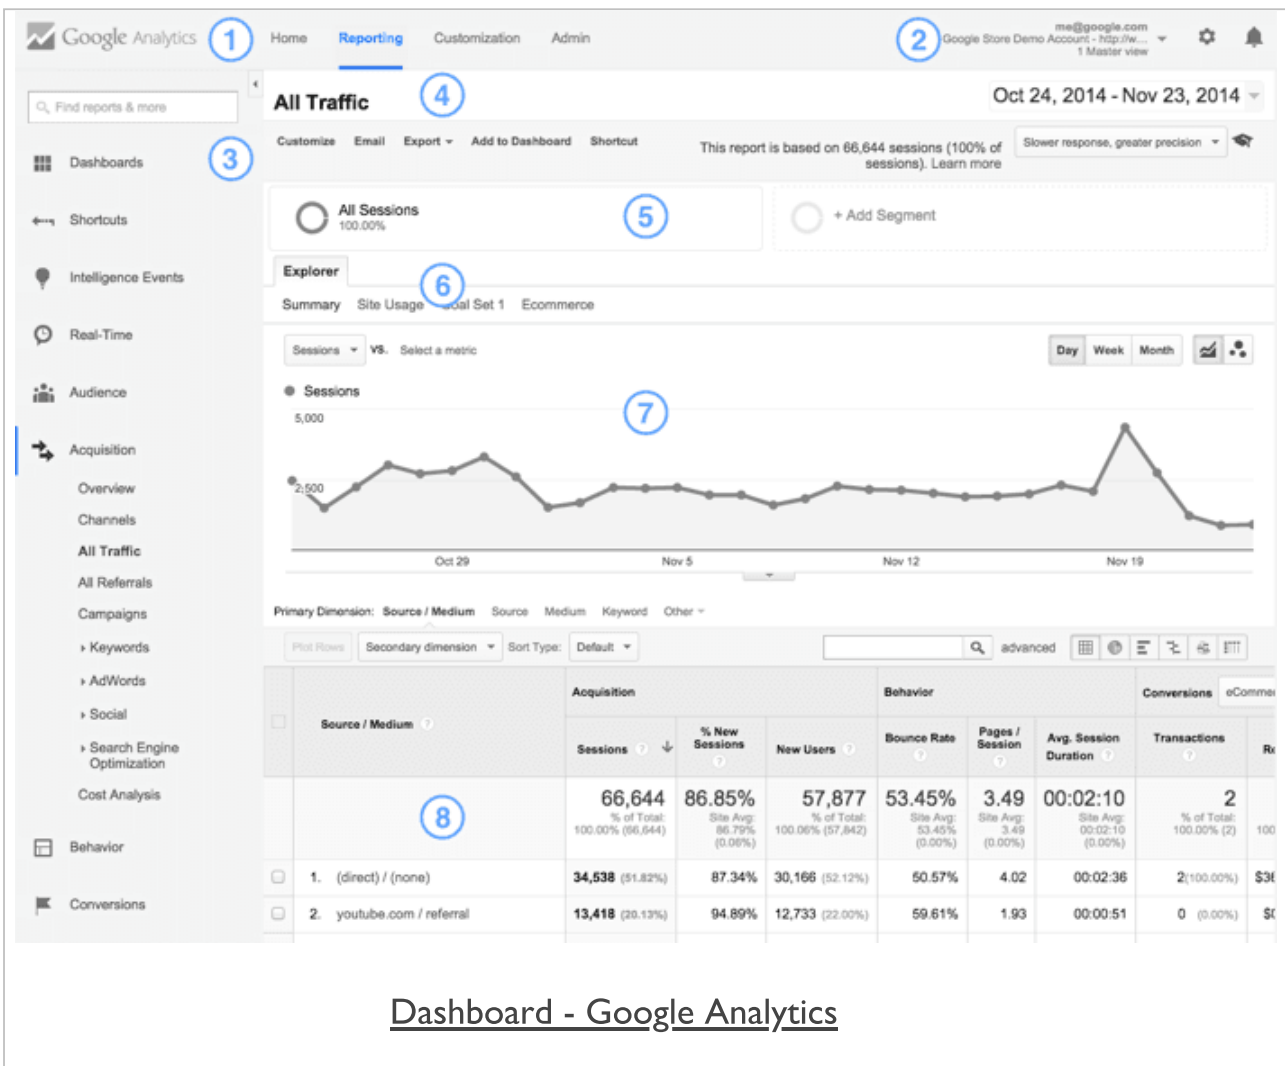

- *relative positioning of elements helps communicate dashboard information*
- *laws of Prägnanz teach us*
- *position can often infer a perception of relationship and similarity*
- *higher items are often perceived as being better*
- *items on the left of the screen traditionally seen first by a western user*

Data visualisation

Building a dashboard

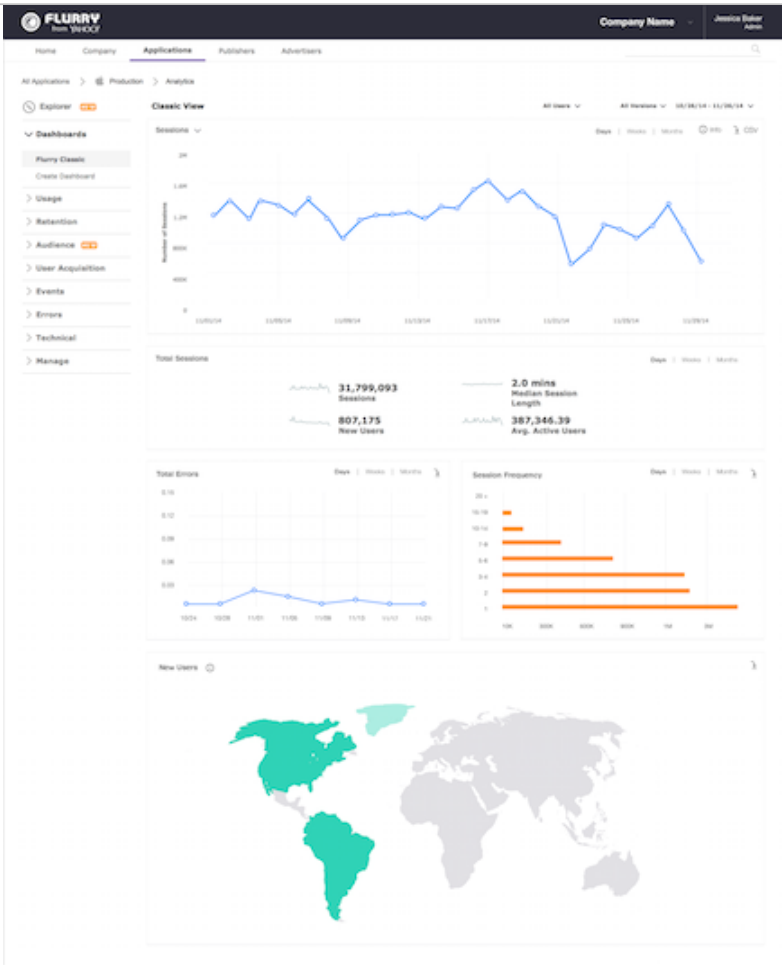

- need to clearly determine the questions that need to be answered
 - *given the information collated and presented within the dashboard*
- need to ensure that any problems can be detected on time
- be certain why we actually need a dashboard for the current dataset
- then begin to collect the requisite data to help us answer such questions
 - *data can be sourced from multiple, disparate datasets*
- chosen visualisations help us tell this story more effectively
- present it in a manner appealing to our users
- need to consider information visualisations familiar to our users
 - *helps reduce any potential user's cognitive overload*
- carefully consider organisation of data and information
- organise the data into logical units of information
 - *helps present dashboard information in a meaningful manner*
- dashboard sections should be organised
 - *to help highlight and detect any underlying or prevailing issues*
 - *then present them to the user*

Dashboard - Mint

Data visualisation - D3

Intro - part I

- D3 is a custom JavaScript library
 - *designed for the manipulation of data centric documents*
 - *uses a custom library with HTML, CSS, and SVG*
 - *creates graphically rich, informative documents for the presentation of data*
- D3 uses a data-driven approach to manipulate the DOM
- Setup and configuration of D3 is straightforward
 - *most involved aspect is the configuration of a web server*
- D3.js works with standard HTML files
 - *requires a web server capable of parsing and rendering HTML...*
- to parse D3 correctly we need
 - *UTF-8 encoding reference in a meta element in the head section of our file*
 - *reference D3 file, CDN in standard script element in HTML*

Data visualisation - D3

intro - part 2

- D3 Wiki describes the underlying functional concepts as follows,

D3's functional style allows code reuse through a diverse collection of components and plugins.

D3 Wiki

- in JS, functions are objects
 - *as with other objects, a function is a collection of a name and value pair*
- real difference between a function object and a regular object
 - *a function can be invoked, and associated, with two hidden properties*
 - *include a function context and function code*
- variable resolution in D3 relies on variable searching being performed locally first
- if a variable declaration is not found
 - *search will continue to the parent object*
 - *continue recursively to the next static parent*
 - *until it reaches global variable definition*
 - *if not found, a reference error will be generated for this variable*
- important to keep this static scoping rule in mind when dealing with D3

Data visualisation - D3

Data Intro - part I

- Data is structured information with an inherent perceived potential for meaning
- consider data relative to D3
 - *need to know how data can be represented*
 - *both in programming constructs and its associated visual metaphor*
- what is the basic difference between data and information?

Data are raw facts. The word raw indicates that the facts have not yet been processed >>> to reveal their meaning...Information is the result of processing raw data to reveal >>> its meaning.

Rob, Morris, and Coronel. 2009

- a general concept of data and information
- consider them relative to visualisation, impart a richer interpretation
- information, in this context, is no longer
 - *the simple result of processed raw data or facts*
 - *it becomes a visual metaphor of the facts*
- same data set can generate any number of visualisations
 - *may lay equal claim in terms of its validity*
- visualisation is communicating creator's insight into data...

Data visualisation - D3

Data Intro - part 2

- relative to development for visualisation
 - *data will often be stored simply in a text or binary format*
- not simply textual data, can also include data representing
 - *images, audio, video, streams, archives, models...*
- for D3 this concept may often simply be restricted to
 - *textual data, or text-based data...*
 - *any data represented as a series of numbers and strings containing alpha numeric characters*
- suitable textual data for use with D3
 - *text stored as a comma-separated value file (.csv)*
 - *JSON document (.json)*
 - *plain text file (.txt)*
- data can then be *bound* to elements within the DOM of a page using D3
 - *inherent pattern for D3*

Data visualisation - D3

Data Intro - Enter-Update-Exit Pattern

- in D3, connection between data and its visual representation
 - usually referred to as the **enter-update-exit** pattern
- concept is starkly different from the standard imperative programming style
- pattern includes
 - enter mode
 - update mode
 - exit mode

Data visualisation - D3

Data Intro - Enter-Update-Exit Pattern

Enter mode

- `enter()` function returns all specified data that not yet represented in visual domain
- standard modifier function chained to a selection method
 - *create new visual elements representing given data elements*
 - *eg: keep updating an array, and outputting new data bound to elements*

Update mode

- `selection.data(data)` function on a given selection
 - *establishes connection between data domain and visual domain*
- returned result of intersection of data and visual will be a **data-bound** selection
- now invoke a modifier function on this newly created selection
 - *update all existing elements*
 - *this is what we mean by an **update** mode*

Exit mode

- invoke `selection.data(data).exit` function on a data-bound selection
 - *function computes new selection*
 - *contains all visual elements no longer associated with any valid data element*
- *eg: create a bar chart with 25 data points*
 - *then update it to 20, so we now have 5 left over*
 - **exit mode** can now remove excess elements for 5 spare data points

Data visualisation - D3

Data Intro - binding data - part I

- consider standard patterns for working with data
- we can iterate through an array, and then bind the data to an element
 - *most common option in D3 is to use the **enter-update-exit** pattern*
- use same basic pattern for binding object literals as data
- to access our data we call the required attribute of the supplied data

```
var data = [  
  {height: 10, width: 20},  
  {height: 15, width: 25}  
];  
  
function (d) {  
  return (d.width) + "px";  
}
```

- then access the **height** attribute per object in the same manner
- we can also bind functions as data
 - *D3 allows functions to be treated as data...*

Data visualisation - D3

Data Intro - binding data - part 2

- D3 enables us to bind data to elements in the DOM
 - *associating data to specific elements*
 - *allows us to reference those values later*
 - *so that we can apply required mapping rules*
- use D3's `selection.data()` method to bind our data to DOM elements
 - *we obviously need some data to bind, and a selection of DOM elements*
- D3 is particularly flexible with data
 - *happily accepts various types*
- D3 also has a built-in function to handle loading JSON data

```
d3.json("testdata.json", function(json) {  
    console.log(json); //do something with the json...  
});
```

Data visualisation - D3

Data Intro - working with arrays - options

- min and max = return the min and max values in the passed array

```
d3.select("#output").text(d3.min(ourArray));  
d3.select("#output").text(d3.max(ourArray));
```

- extent = retrieves both the smallest and largest values in the the passed array

```
d3.select("#output").text(d3.extent(ourArray));
```

- sum

```
d3.select("#output").text(d3.sum(ourArray));
```

- median

```
d3.select("#output").text(d3.median(ourArray));
```

- mean

```
d3.select("#output").text(d3.mean(ourArray));
```

- asc and desc

```
d3.select("#output").text(ourArray.sort(d3.ascending));  
d3.select("#output").text(ourArray.sort(d3.descending));
```

- & many more...

Data visualisation - D3

Data Intro - working with arrays - nest

- D3's nest function used to build an algorithm
 - *transforms a flat array data structure into a hierarchical nested structure*
- function can be configured using the key function chained to **nest**
- nesting allows elements in an array to be grouped into a hierarchical tree structure
 - *similar in concept to the group by option in SQL*
 - **nest** allows multiple levels of grouping
 - *result is a tree rather than a flat table*
- levels in the tree are defined by the key function
- leaf nodes of the tree can be sorted by value
- internal nodes of the tree can be sorted by key

Data visualisation - D3

Selections - intro

- **Selection** is one of the key tasks required within D3 to manipulate and visualise our data
- simply allows us to target certain visual elements on a given page
- Selector support is now standardised upon the W3C specification for the **Selector API**
 - *supported by all of the modern web browsers*
 - *its limitations are particularly noticeable for work with visualising data*
- Selector API only provides support for selector and not selection
 - *able to select an element in the document*
 - *to manipulate or modify its data we need to implement a standard loop etc*
- D3 introduced its own selection API to address these issues and perceived shortcomings
 - *ability to select elements by ID or class, its attributes, set element IDs and class, and so on...*

Data visualisation - D3

Selections - single element

- select a single element within our page

```
d3.select("p");
```

- now select the first <p> element on the page, and then allow us to modify as necessary
 - *eg; we could simply add some text to this element*

```
d3.select("p")  
.text("Hello World");
```

- selection could be a generic element, such as <p>
 - *or a specific element defined by targeting its ID*
- use additional modifier functions, such as `attr`, to perform a given modification on the selected element

```
//set an attribute for the selected element  
d3.select("p").attr("foo");  
//get the attribute for the selected element  
d3.select("p").attr("foo");
```

- also add or remove classes on the selected element

```
//test selected element for specified class  
d3.select("p").classed("foo")  
//add a class to the selected element  
d3.select("p").classed("goo", true);  
//remove the specified class from the selected element  
d3.select("p").classed("goo", function(){ return false; });
```

Data visualisation - D3

Selections - multiple elements

- also select all of the specified elements using D3

```
d3.selectAll("p")  
.attr("class", "para");
```

- use and implement multiple element selection
 - *same as single selection pattern*
- also use the same modifier functions
- allows us to modify each element's attributes, style, class...

Data visualisation - D3

Selections - iterating through a selection

- D3 provides us with a selection iteration API
 - *allows us to iterate through each selection*
 - *then modify each selection relative to its position*
 - *very similar to the way we normally loop through data*

```
d3.selectAll("p")
  .attr("class", "para")
  .each(function (d, i) {
    d3.select(this).append("h1").text(i);
  });
```

- D3 selections are essentially like arrays with some enhancements
 - *use the iterative nature of Selection API*

```
d3.selectAll('p')
  .attr("class", "para2")
  .text(function(d, i) {
    return i;
  });
```

Data visualisation - D3

Selections - performing sub-selection

- for selections - often necessary to perform specific scope requests
 - *eg: selecting all <p> elements for a given <div> element*

```
//direct css selector (selector level-3 combinators)  
d3.select("div > p")  
  .attr("class", "para");  
  
//d3 style scope selection  
d3.select("div")  
  .selectAll("p")  
  .attr("class", "para");
```

- both examples produce the same effect and output, but use very different selection techniques
 - *first example uses the CSS3, level-3, selectors*
 - *div > p is known as combinators in CSS syntax*

Data visualisation - D3

Selections - combinators

Example combinators..

1. descendant combinator

- uses the pattern of `selector selector` - describing loose parent-child relationship
- loose due to possible relationships - parent-child, parent-grandchild...

```
d3.select("div p");
```

- select the `<p>` element as a child of the parent `<div>` element
 - *relationship can be generational*

2. child combinator

- uses same style of syntax, `selector > selector`
- able to describe a more restrictive **parent-child** relationship between two elements

```
d3.select("div > p");
```

- finds `<p>` element if it is a direct child to the `<div>` element

Data visualisation - D3

Selections - D3 sub-selection

- sub-selection using D3's built-in selection of child elements
- a simple option to select an element, then chain another selection to get the child element
- this type of chained selection defines a scoped selection within D3
 - eg: selecting a `<p>` element nested within our selected `<div>` element
 - each selection is, effectively, independent
- D3 API built around the inherent concept of function chaining
 - can almost be considered a Domain Specific Language for dynamically building HTML/SVG elements
- a benefit of chaining = easy to produce concise, readable code

```
var body = d3.select("body");

body.append("div")
  .attr("id", "div1")
  .append("p")
  .attr("class", "para")
  .append("h5")
  .text("this is a paragraph heading...");
```

Data visualisation - D3

Data Intro - page elements

- generation of new DOM elements normally fits
 - *either circles, rectangles, or some other visual form that represents the data*
- D3 can also create generic structural elements in HTML, such as a `<p>`
 - *eg: we can append a standard `p` element to our new page*

```
d3.select("body").append("p").text("sample text...");
```

- used D3 to select body element, then append a new `<p>` element with text "new paragraph"
- D3 supports *chain syntax*
 - *allowed us to select, append, and add text in one statement*

Data visualisation - D3

Data Intro - page elements

```
d3.select("body").append("p").text("sample text...");
```

- `d3`
 - *references the D3 object, access its built-in methods*
- `.select("body")`
 - *accepts a CSS selector, returns first instance of the matched selector in the document's DOM*
 - `.selectAll()`
 - **NB:** *this method is a variant of the single `select()`*
 - *returns all of the matched CSS selectors in the DOM*
- `.append("p")`
 - *creates specified new DOM element*
 - *appends it to the end of the defined select CSS selector*
- `.text("new paragraph")`
 - *takes defined string, "new paragraph"*
 - *adds it to the newly created `<p>` DOM element*

Data visualisation - D3

Binding data - making a selection

- choose a selector within our document
 - eg: we could select all of the paragraphs in our document

```
d3.select("body").selectAll("p");
```

- if the element we require does not yet exist
 - need to use the method `enter()`

```
d3.select("body").selectAll("p").data(dataset).enter().append("p").text("new para
```

- we get new paragraphs that match total number of values currently available in the **dataset**
 - akin to looping through an array
 - outputting a new paragraph for each value in the array
- create new, data-bound elements using `enter()`
 - method checks the current DOM selection, and the data being assigned to it
- if more data values than matching DOM elements
 - `enter()` creates a new placeholder element for the data value
 - then passes this placeholder on to the next step in the chain, eg: `append()`
- data from dataset also assigned to new paragraphs
- **NB:** when D3 binds data to a DOM element, it does not exist in the DOM itself
 - it does exist in the memory

Data visualisation - D3

Binding data - using the data

- change our last code example as follows,

```
d3.select("body").selectAll("p").data(dataset).enter().append("p").text(function(d
```

- then load our HTML, we'll now see dataset values output instead of fixed text
- anytime in the chain after calling the `data()` method
 - we can then access the current data using *d*
- also bind other things to elements with D3, eg: CSS selectors, styles...

```
.style("color", "blue");
```

- chain the above to the end of our existing code
 - now bind an additional css style attribute to each `<p>` element
 - turning the font colour blue
- extend code to include a conditional statement that checks the value of the data
 - eg: *simplistic striped colour option*

```
.style("color", function(d) {  
  if (d % 2 == 0) {  
    return "green";  
  } else {  
    return "blue";  
  }  
});
```

Data visualisation - D3

Drawing - intro - part I

1. drawing divs

- one of the easiest ways to draw a rectangle, for example, is with a HTML `<div>`
- an easy way to start drawing a bar chart for our stats
- start with standard HTML elements, then consider more powerful option of drawing with SVG
- semantically incorrect, we could use `<div>` to output bars for a bar chart
 - *use of an empty `<div>` for purely visual effect*
- using D3, add a class to an empty element using `selection.attr()` method

2. setting attributes

- `attr()` is used to set an HTML attribute and its value on an element
- After selecting the required element in the DOM
 - *assign an attributes as follows*

```
.attr("class", "barchart")
```

Data visualisation - D3

Drawing - intro - part 2

- use D3 to draw a set of bars in divs as follows

```
var dataset = [ 1, 2, 3, 4, 5 ];

d3.select("body").selectAll("div")
  .data(dataset)
  .enter()
  .append("div")
  .attr("class", "bar");
```

- above sample outputs the values from our dataset with no space between them
 - *effectively as a bar chart of equal height*
- modify the height of each representative bar
 - *by setting height of each bar as a function of its corresponding data value*
 - *eg: append the following to our example chain*

```
.style("height", function(d) {
  return d + "px";
});
```

- make each bar in our chart more clearly defined by modifying style

```
.style("height", function(d) {
  var barHeight = d * 3;
  return barHeight + "px";
});
```

Data visualisation - D3

Drawing - intro - part 3

1. drawing SVGs

- properties of SVG elements are specified as **attributes**
- represented as property/value pairs within each element tag

```
<element property="value">...</element>
```

- SVG elements exist in the DOM
 - we can still use D3 methods *append()* and *attr()*
 - create new HTML elements and set their attributes

2. create SVG

- need to create an element for our SVG
- allows us to draw and output all of our required shapes

```
d3.select("body").append("svg");
```

- variable effectively works as a reference
 - points to the newly created SVG object
 - allows us to use this reference to access this element in the DOM
- DEMO - Drawing with SVG

genius is 1% inspiration, 99% perspiration

[Basic drawing - add circles](#)

[Basic drawing - add rectangles](#)

[D3 - basic drawing](#)

Data visualisation - D3

Drawing - SVG barchart - part I

- create a new barchart using SVG, need to set the required size for our SVG output

```
//width & height  
var w = 750;  
var h = 200;
```

- then use D3 to create an empty SVG element, and add it to the DOM

```
var svg = d3.select("body")  
  .append("svg")  
  .attr("width", w)  
  .attr("height", h);
```

- instead of creating DIVs as before, we generate *rects* and add them to the svg element.

```
svg.selectAll("rect")  
  .data(dataset)  
  .enter()  
  .append("rect")  
  .attr("x", 0)  
  .attr("y", 0)  
  .attr("width", 10)  
  .attr("height", 50);
```

Data visualisation - D3

Drawing - SVG barchart - part 2

- this code selects all of the `rect` elements within `svg`
- initially none, D3 still needs to select them before creating them
- `data()` then checks the number of values in the specified dataset
 - *hands those values to the `enter` method for processing*
- `enter` method then creates a placeholder
 - *for each data value without a corresponding `rect`*
 - *also appends a rectangle to the DOM for each data value*
- then use `attr` method to set `x`, `y`, `width`, `height` values for each rectangle
- still only outputs a single bar due to an overlap issue
- need to amend our code to handle the width of each bar
 - *implement flexible, dynamic coordinates to fit available SVG width and height*
 - *visualisation scales appropriately with the supplied data*

```
.attr("x", function(d, i) {  
    return i * (w / dataset.length);  
})
```

Data visualisation - D3

Drawing - SVG barchart - part 3

- now linked the x value directly to the width of the SVG w
 - and the number of values in the dataset, `dataset.length`
 - the bars will be evenly spaced regardless of the number of values
- if we have a large number of data values
 - bars still look like one horizontal bar
 - unless there is sufficient width for parent SVG and space between each bar
- try to solve this as well by setting the bar width to be proportional
 - narrower for more data, wider for less data

```
var w = 750;  
var h = 200;  
var barPadding = 1;
```

- now set each bar's width
 - as a fraction of the SVG width and number of data points, minus our padding value

```
.attr("width", w / dataset.length - barPadding)
```

- our bar widths and x positions scale correctly regardless of data values

Data visualisation - D3

Drawing - SVG barchart - part 4

- encode our data as the *height* of each bar

```
.attr("height", function(d) {  
    return d * 4;  
});
```

- our bar chart will size correctly, albeit from the top down
 - *due to the nature of SVG*
 - *SVG adheres to a top left pattern for rendering shapes*
- to correct this issue
 - *need to calculate the top position of our bars relative to the SVG*
- top of each bar expressed as a relationship
 - *between the height of the SVG and the corresponding data value*

```
.attr("y", function(d) {  
    //height minus data value  
    return h - d;  
});
```

- bar chart will now display correctly from the bottom upwards

Testing - D3

[Home](#) | [d3 data drawing bar](#)

Bar chart 1 - no correction

Bar chart 2 - correction

D3 - drawing barcharts

Data visualisation - D3

Drawing - SVG barchart - part 5

1. add some colour

- adding a colour per bar simply a matter of setting an attribute for the fill colour

```
.attr("fill", "blue");
```

- set many colours using the data itself to determine the colour

```
.attr("fill", function(d) {  
    return "rgb(0, 0, " + (d * 10) + ")";  
});
```

2. add text labels

- also set dynamic text labels per bar, which reflect the current dataset

```
svg.selectAll("text")  
  .data(dataset)  
  .enter()  
  .append("text")
```

- extend this further by positioning our text labels

```
.attr("x", function(d, i) {  
    return i * (w / dataset.length);  
})  
.attr("y", function(d, i) {  
    return h - (d * 4);  
});
```

- then position them relative to the applicable bars, add some styling, colours...

```
.attr("font-family", "sans-serif")  
.attr("font-size", "11px")  
.attr("fill", "white");
```

D3 - drawing barcharts with colour and text

Data visualisation - D3

Drawing - add interaction - listeners

- event listeners apply to any DOM element for interaction
 - *from a button to a `<p>` with the body of a HTML page*

```
<p>this is a HTML paragraph...</p>
```

- add a listener to this DOM element

```
d3.select("p")  
  .on("click", function() {  
    //do something with the element...  
  });
```

- above sample code selects the `<p>` element
 - *then adds an event listener to that element*
- event listener is an anonymous function
 - *listens for `.on` event for a specific element or group of elements*
- in our example,
 - *`on ()` function takes two arguments*

Data visualisation - D3

Drawing - add interaction - update visuals

- achieved by combining
 - *event listener*
 - *modification of the visuals relative to changes in data*

```
d3.select("p")
  .on("click", function() {

    dataset = [...];

    //update all of the rects
    svg.selectAll("rect")
      .data(dataset)
      .attr("y", function(d) {
        return h - yScale(d);
      });
      .attr("height", function(d) {
        return yScale(d);
      });
  });
```

- above code triggers a change to visuals for each call to the event listener
- eg: change the colours
 - *add call to `fill()` to update bar colours*

```
.attr("fill", function( d) {
  return "rgb( 0, 0, " + (d * 10) + ")";
});
```

- DEMO - update bar colours

Image - D3 Barcharts

Bar chart 3 - colours

D3 - drawing colour updates for barcharts

Data visualisation - D3

Drawing - add interaction - transitions

- adding a fun transition in D3 is as simple as adding the following,

```
.transition()
```

- add this to above code chain to get a fun and useful transition in the data
- animation reflects the change from the old to the new data
- add a call to the `duration()` function
 - *allows us to specify a time delay for the transition*
 - *quick, slow...we can specify each based upon time*
- chain the `duration()` function after `transition()`

```
.transition().duration(1000)
```

- if we want to specify a constant easing to the transition
 - *use `ease()` with a `linear` parameter*

```
.ease(linear)
```

- other built-in options, including
 - *circle - gradual ease in and acceleration until elements snap into place*
 - *elastic - best described as springy*
 - *bounce - like a ball bouncing, and then coming to rest...*

Data visualisation - D3

Drawing - add interaction - transitions

- add a delay using the `delay()` function

```
.transition()  
.delay(1000)  
.duration(2000)
```

- also set the `delay()` function dynamically relative to the data,

```
.transition()  
.delay( function( d, i ) {  
  return i * 100;  
})  
.duration( 500)
```

- when passed an anonymous function
 - *datum bound to the current element is passed into `d`*
 - *index position of that element is passed into `i`*
- in the above code example, as D3 loops through each element
 - *delay for each element is set to `i * 100`*
 - *meaning each subsequent element will be delayed 100ms more than preceding element*
- DEMO - transitions - interactive sort

Data visualisation - D3

Drawing - add interaction - adding values and elements

- select all of the bars in our chart
 - we can rebind the new data to those bars
 - and grab the new update as well

```
var bars = svg.selectAll("rect")  
  .data(dataset);
```

- if more new elements, bars in our example, than original length
 - use *enter()* to create references to those new elements that do not yet exist
- with these reserved elements
 - we can use *append()* to add those new elements to the DOM
 - now updates our bar chart as well
- now made the new `rect` elements
 - need to update all visual attributes for our *rects*
 - set *x*, and *y* position relative to new dataset length
 - set width and height based upon new *xScale* and *yScale*
 - calculated from new dataset length

Data visualisation - D3

Drawing - add interaction - removing values and elements

- more DOM elements than provided data values
 - D3's **exit** selection contains references to those elements without specified data
 - **exit** selection is simply accessed using the `exit()` function
- grab the exit selection
- then transition exiting elements off the screen
 - *for example to the right*
- then finally remove it

```
bars.exit()  
  .transition()  
  .duration(500)  
  .attr("x", w)  
  .remove();
```

- `remove()` is a special transition method that awaits until transition is complete
- then deletes element from DOM forever
 - *to get it back, we'd need to rebuild it again*

Data visualisation - D3

Drawing - SVG scatterplot - intro

- scatterplot allows us to visualise two sets of values on two different axes
 - *one set of data against another*
- plot one set of data on x axis, and the other on the y axis
- often create dimensions from our data
 - *helps us define patterns within our dataset*
 - *eg: date against age, or age against fitness...*
- dimensions will also be represented relative to x and y axes
- create our scatterplot using SVG
 - *add our SVG to a selected element*

Image - D3 Scatterplot

Testing - D3

[Home](#) | [d3 data drawing scatter](#)

[D3 - drawing a basic scatterplot](#)

Data visualisation - D3

Drawing - SVG scatterplot - data

- data for the scatterplot is normally stored as a multi-dimensional representation
 - *comparison x and y points*
- eg: we could store this data in a multi-dimensional array

```
var dataset = [  
  [10, 22], [33, 8], [76, 39], [4, 15]  
];
```

- in such a multi-dimensional array
 - *inner array stores the comparison data points for our scatterplot*
 - *each inner array stores x and y points for scatterplot diagram*
- we can also store such data in many different structures
 - eg: JSON...

Data visualisation - D3

Drawing - SVG scatterplot - create SVG

- need to create an element for our SVG
 - *allows us to draw and output all of our required shapes*

```
d3.select("body").append("svg");
```

- appends to the body an SVG element
 - *useful to encapsulate this new DOM element within a variable*

```
var svg = d3.select("body").append("svg");
```

- variable effectively works as a reference
 - *points to the newly created SVG object*
 - *allows us to use this reference to access element in the DOM*

Data visualisation - D3

Drawing - SVG scatterplot - build scatterplot

- as with our barchart, we can set the width and height for our scatterplot,

```
//width & height  
var w = 750;  
var h = 200;
```

- we will need to create circles for use with scatterplot instead of rectangles

```
svg.selectAll('circle')  
  .data(dataset)  
  .enter()  
  .append('circle');
```

- corresponding to drawing circles
 - set cx , the x position value of the centre of the circle
 - set cy , the y position value of the centre of the circle
 - set r , the radius of the circle

Data visualisation - D3

Drawing - SVG scatterplot - adding circles

- draw circles for scatterplot

```
.attr('cx', function(d) {  
    return d[0]; //get first index value for inner array  
})  
.attr('cy', function(d) {  
    return d[1]; //get second index value for inner array  
})  
.attr('r', 5);
```

- outputs simple circle for each inner array within our supplied multi-dimensional dataset
- start to work with creating circle sizes relative to data quantities
- set a dynamic size for each circle
 - *representative of the data itself*
 - *modify the circle's area to correspond to its y value*
- as we create SVG circles, we cannot directly set the area
 - *so we need to calculate the radius r*
 - *then modify that for each circle*

Data visualisation - D3

Drawing - SVG scatterplot - calculate dynamic area

- assuming that `d[1]` is the original area value of our circles
 - *get the square root and set the radius for each circle*
- instead of setting each circle's radius as a static value
 - *now use the following*

```
.attr('r', function(d) {  
    return Math.sqrt(d[1]);  
});
```

- use the JavaScript `Math.sqrt()` function to help us with this calculation

Data visualisation - D3

Drawing - SVG scatterplot - add colour

- as with a barchart
- also set a dynamic colour relative to a circle's data

```
.attr('fill', function (d) {  
    return 'rgb(125,' + (d[1]) + ', ' + (d[1] * 2) + ');'  
});
```

Data visualisation - D3

Drawing - SVG scatterplot - add labels

```
//add labels for each circle
svg.selectAll('text')
  .data(dataset)
  .enter()
  .append('text')
  .text(function(d) {
    return d[0] + ', ' + d[1]; //set each data point on the text label
  })
  .attr('x', function(d) {
    return d[0];
  })
  .attr('y', function(d) {
    return d[1];
  })
  .attr('font-family', 'serif')
  .attr('font-size', '12px')
  .attr('fill', 'navy');
```

- start by adding text labels for our data
 - *adding new text elements where they do not already exist*
- then set the text label itself for each circle
 - *using the data values stored in each inner array*
- make the label easier to read
 - *set x and y coordinates relative to data points for each circle*
- set some styles for the labels

Image - D3 Scatterplot

Testing - D3

[Home](#) | [d3 data drawing scales](#)

D3 - drawing a basic scatterplot 2

Data visualisation - D3

Drawing - SVG - scales

- in D3, scales are defined as follows,

"Scales are functions that map from an input domain to an output range"

Bostock, M.

- you can specify your own scale for the required dataset
 - *eg: to avoid massive data values that do not translate correctly to a visualisation*
 - *scale these values to look better within you graphic*
- to achieve this result, you simply use the following pattern.
 - *define the parameters for the scale function*
 - *call the scale function*
 - *pass a data value to the function*
 - *the scale function returns a scaled output value for rendering*
- also define and use as many scale functions as necessary for your visualisation
- important to realise that a scale has no direct relation to the visual output
 - *it is a mathematical relationship*
- need to consider scales and axes
 - *two separate, different concepts relative to visualisations*

Data visualisation - D3

Drawing - SVG - domains and ranges

- *input domain* for a scale is its possible range of input data values
 - *in effect, initial data values stored in your original dataset*
- *output range* is the possible range of output values
 - *normally use as the pixel representation of the data values*
 - *a personal consideration of the designer*
- normally set a minimum and maximum *output range* for our scaled data
- scale function then calculates the scaled output
 - *based upon original data and defined range for scaled output*
- many different types of scale available for use in D3
- three primary types
 - *quantitative*
 - *ordinal*
 - *time*
- *quantitative* scale types also include other built-in scale types
- many methods available for the scale types

Data visualisation - D3

Drawing - SVG - building a scale

- start building our scale in D3
 - use `d3.scale` with our preferred scale type

```
var scale = d3.scale.linear();
```

- to use the scale effectively, we now need to set our input domain

```
scale.domain([10, 350]);
```

- then we set the output range for the scale

```
scale.range([1, 100]);
```

- we can also chain these methods together

```
var scale = d3.scale.linear()  
  .domain([10, 350])  
  .range([1, 100]);
```

Data visualisation - D3

Drawing - SVG - adding dynamic scales

- we could pre-define values for our scale relative to a given dataset
- makes more sense to abstract these values relative to the defined dataset
- we can now use the D3 array functions to help us set these scale values
 - *eg; find highest number in array dataset*

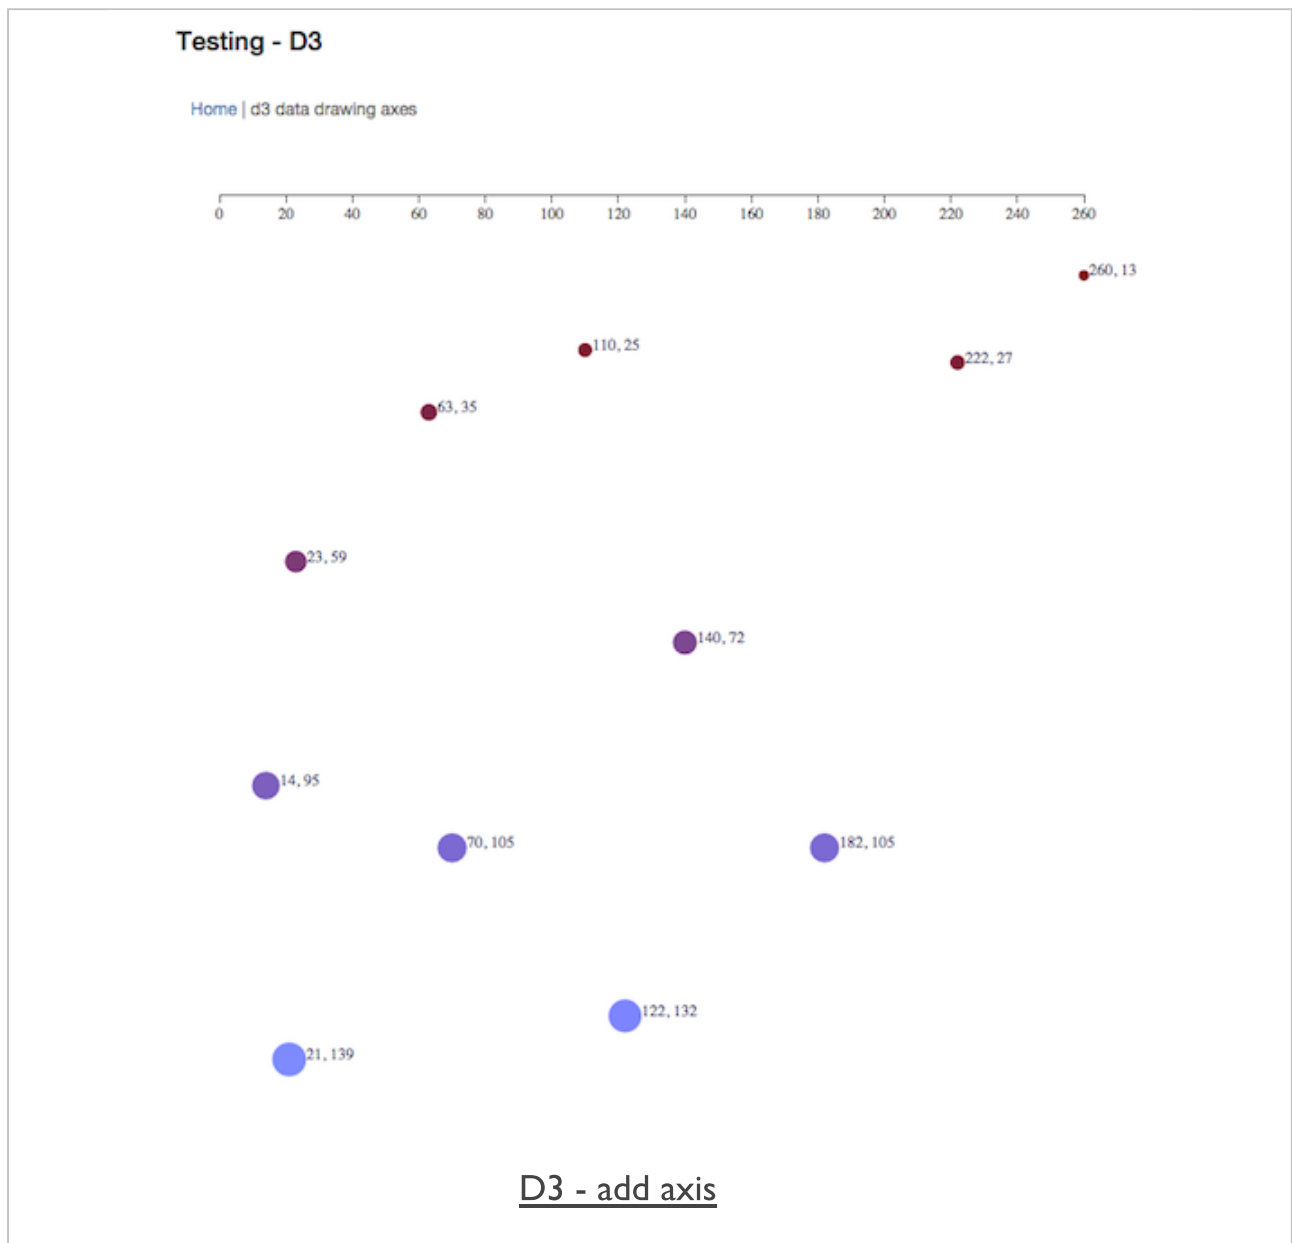

```
d3.max(dataset, function(d) {  
    return d[0];  
});
```

- returns highest value from the supplied array
- getting minimum value in array works in the same manner
 - *with d3.min() being called instead*
- now create a scale function for x and y axes

```
var scaleX = d3.scale.linear()  
    .domain([0, d3.max(dataset, function(d) { return d[0]; })])  
    .range([0, w]); //set output range from 0 to width of svg
```

- Y axis scale modifies above code relative to provided data, d[1]
 - *range uses height instead of width*
- for a scatterplot we can use these values to set cx and cy values
